

AI Disclosure — HoneyMoney

Team JUST50 · Updated 27 August 2026 ·

AI use in HoneyMoney

HoneyMoney uses AI only as an optional assistance layer; it does not calculate financial figures, move money, execute transactions, or recommend financial products. All financial arithmetic, scores, forecasts and budget figures are generated by deterministic code. AI may only help parse information or phrase an explanation. Every number in an AI response is checked against the verified computed data; if an unrecognised number appears, the response is rejected and replaced with a fixed template. Insights are educational only, not licensed financial advice; product advice is routed to licensed providers or directories.

By default, receipt OCR, text parsing and category classification run on-device using Tesseract and HoneyMoney's own parser, so no data leaves the device and no AI tokens are used. Gemini Flash may be used only when a user chooses optional image extraction; it receives only the selected image. Groq may be used only to phrase a response and receives limited structured context—such as slot names, intent and locale—without financial figures, labels or free text. Users may also run Ollama locally on their own hardware, where full context remains on their machine.

Development and assurance

Claude Code by Anthropic supported coding and AI-assisted development workflows. The HoneyMoney team reviewed and accepted the architecture, financial model and user-facing content. The public, non-backdated commit history records the development process. Automated checks support key claims: check:ask verifies that AI cannot introduce unsupported financial figures; check:vault verifies that plaintext does not enter encrypted backups; and check:capture verifies that stored data matches user input.

Data, infrastructure and consent

GitHub provides source-code hosting, version control and review, and holds no customer data. Cloudflare Tunnel proxies traffic to the app server, while Cloudflare Pages serves a static snapshot without personal data. Cloudflare R2 stores nightly backups encrypted with AES-256-GCM in the browser before upload, so Cloudflare stores ciphertext only. PocketBase is self-hosted and provides the application database, authentication and migrations; it stores the household knowledge graph in superuser-only collections that are not directly accessible from a browser.

AI is disabled until a household explicitly enables it for a stated purpose. Consent is recorded append-only, can be withdrawn, and is enforced at the point of use. Encrypted backups are sealed in the browser with a passphrase HoneyMoney does not receive. However, the live application database is readable by the server because it must compute dashboard scores and forecasts; HoneyMoney discloses this limitation clearly. HoneyMoney sells software, not personal data: it provides no brokerage, advertising, or “anonymised insights” product. If a statement in this disclosure becomes inaccurate, it will be corrected promptly.
